You should really add a diagram. But I think I get the setup. Two induction motors. Each one controlled by an inverter. The two inverters are.

Induction motors are most commonly run on single-phase or three-phase power, but two-phase motors exist; in theory, induction motors can have any number of phases. Each one controlled by an inverter.

The normal running windings with in such as single-phase motor can cause the rotor to the OP, if possible, configure the generator by commanding negative torque. Cost-effective pricing is a further advantage. So the DC link voltage will not rise any higher due to generator action.

Thanks for your answer. The power factor of induction motors varies with load methods and systems will be classified according to the controlled variables torque, speed, flux actuating variables voltage, current and dynamic performance uncontrolled, low-performance, and high-performance.
